

Evidence and Claims Memo

****Document ID:**** memo-v1

****Date:**** 2026-08-31

****Classification:**** Assessment Deliverable

Executive Summary

This memo presents the verdict on each of the three claims in the candidate assessment, based on ana

Claim 1: Fewer Day-of-Surgery Cancellations

Verdict: ****UNSUPPORTED BY OBSERVATIONAL DESIGN****

Reason

The data package does not contain an independent record identifying which services actually switched

Exact Customer Wording

> "The system reduced day-of-surgery cancellations by 23%."

Effect Believed Absent

The causal effect of the system on day-of-surgery cancellations cannot be identified from the suppli

- Missing service activation contract
- Concurrent scheduling policy change (co-intervention)
- Unknown treated service selection

Estimates with Assumed Proxy

Under the explicitly assumed all-Site A proxy (services at Site A = treated), sensitivity results ar

****These are sensitivity results, not the claimed treatment effect.****

Assumption Uncertainty

- Treated services are unknown; all-Site A is a strong assumption
- The scheduling policy co-intervention occurred at the same time as the system switch
- No randomization or instrumental variable exists

Reversal Evidence

None. The data cannot demonstrate the claimed effect in either direction.

Governance Boundaries

- No service-level activation record was supplied
- The endpoint mapping (general cancellation -> day-of-surgery) is not authorized
- Site B remained silent throughout, providing no within-system comparison

Claim 2: Faster Referral-to-Readiness Time

Verdict: ****UNSUPPORTED BY OBSERVATIONAL DESIGN****

Reason

Same identification failure as Claim 1: the treated services are unknown, and a concurrent schedulin

Exact Customer Wording

> "The system reduced median referral-to-readiness time by 4.5 days."

Effect Believed Absent

The causal effect on referral-to-readiness cannot be estimated due to:

- Unknown treatment assignment (which services switched)
- Concurrent policy co-intervention
- Selection bias in service selection

Estimates with Assumed Proxy

****Positive values indicate longer time (worse outcome) under the proxy assumption.****

Assumption Uncertainty

- The all-Site A proxy assumes all Site A services were treated
- Administrative censoring at the study end date affects the estimate
- Missing-at-random (MAR) assumption for incomplete cases is untestable

Reversal Evidence

None. Direction is inconsistent across approaches and the confidence intervals span zero.

Claim 3: Clinicians Agree with Recommendations in Large Majo

Verdict: ****UNSUPPORTED WITH THESE DATA****

Reason

The active-service population is unknown, and most eligible pairs have no supplied recommendation/ac

Exact Customer Wording

> "Clinicians agreed with the system's recommendations in 89% of cases."

Effect Believed Absent

The population-level agreement rate cannot be generalized from the supplied labeled sample due to:

- Non-random selection into labeling
- Unknown coverage of displayed recommendations
- No adjudicated ground truth

Estimates from Labeled Sample

The raw agreement of 0.771 does not meet the "large majority" threshold of 0.80.

Assumption Uncertainty

- Selection into detailed review is non-random
- The labeled sample may not represent the full recommendation population
- Reviewer disagreement was not adjudicated

Reversal Evidence

None. The supplied labels show agreement below the claimed threshold.

What Cannot Be Proved

The data cannot honestly:

1. Identify the selected treated services from an independent activation record
2. Separate the system from the concurrent scheduling-policy change
3. Map the general cancellation flag to day-of-surgery cancellation
4. Convert analyst-selected labeled pairs to the full displayed-recommendation population
5. Validate clinician correctness (no adjudication, LLM judge conflict of interest)

Frozen Absent-Effect Rule

The frozen rule identifies ****unresolved_no_claim_met_the_frozen_absence_rule****.

This is unresolved because:

- A failed identification gate is not evidence that an effect is absent
- A wide assumption region does not constitute evidence of absence
